

SAMPLING THE DEMERSAL FAUNA FROM A COMMERCIAL PENAEID PRAWN FISHERY OFF THE CENTRAL QUEENSLAND COAST

CLIVE M. JONES and KURT DERBYSHIRE

Jones, C. M. and Derbyshire, K. 1988 11 7: Sampling the demersal fauna from a commercial penaeid prawn fishery off the central Queensland coast. *Mem. Qd Mus.* 25(2): 403-415. Brisbane. ISSN 0079-8835.

Two hundred and eighty-one trawl samples (mean weight 35 kg) of benthic fish and invertebrates were gathered from an area of approximately 10,000 square km adjacent to the central Queensland coast, between January 1985 and June 1986. This area is presently subjected to seasonal fishing pressure by commercial prawn trawlers. Samples were taken from 24 fixed stations representing depths from 15 to 62 m, and a variety of bottom types. Of 477 taxa identified, 18 were commercially important. Despite the proximity of coral reefs, the fauna was dissimilar to the 'reef fauna' characteristic of the Great Barrier Reef. The results suggest a strong association between the demersal trawl faunas of north-eastern Australia and the Southeast Asian regions.

□ *Benthic fauna, demersal fauna, trawling, fishing, Great Barrier Reef, coral reef, faunal survey.*

Clive M. Jones and Kurt Derbyshire, Queensland Department of Primary Industries, Northern Fisheries Research Centre, PO Box 5396, Cairns Mail Centre, Queensland 4871; 3 December, 1987.

The prawn trawl fishery off Queensland's eastern central coast, between Lucinda and Bowen (18°30'S to 20°S), is characterised by two seasons, each representing specific areas of exploitation and target species. From March through to June, fishing effort is centred on the inshore coastal fringe in 10 to 30 m depth for tiger prawns (*Penaeus esculentus* and *P. semisulcatus*). Towards the end of this season, however, fishing effort shifts eastwards into deeper waters where king prawns (*P. longistylus* and *P. latisulcatus*) are sufficiently abundant to support fishing through to October (Robertson and Dredge, 1986). Two separate fisheries are thus recognised, the 'tiger prawn' fishery and the 'king prawn' fishery. Several important 'by-catch' species are also caught incidentally to the target species of each fishery. Although many prawn trawl fisheries are characterised by a similar seasonal and spatial transfer of effort, this fishery is unusual in that much of the fishing effort directed at king prawns is expended in the vicinity of coral reefs of the Great Barrier Reef complex.

As the king prawn fishery has developed over the past decade, fishing effort has expanded further eastwards into previously unfished areas and closer to individual reefs. The benthic faunal composition of these areas is poorly documented (Cannon and Goeden, 1982). Consequently, the trawl catch of the fishery is of

considerable interest both to benthic community ecologists (see Cannon *et al.*, 1987) and to the managers of the Great Barrier Reef Marine Park. A comprehensive description of the benthic community subjected to trawling activity is essential to the assessment of fishing impact on adjacent coral reefs. The Queensland Department of Primary Industries initiated a survey of the commercially fished area in 1985. This paper provides details of the methods employed and species composition of the fishery. A second paper (Watson and Goeden, M.S.) examines the species diversity and spatial and temporal distribution of species.

METHODS

Monthly samples of trawl catch were gathered from 20 sites representative of both the tiger prawn and king prawn areas of the fishery (Fig. 1), during 1985. From January to June 1986, monthly sampling was continued at seven of these sites and was started at another four. Sampling was intentionally biased towards the king prawn grounds within inter-reef waters where the benthic faunal composition was of greatest interest. This sampling strategy jointly satisfied the requirements of the demersal fauna research program and of parallel Departmental programs concerned specifically with the commercial catch.

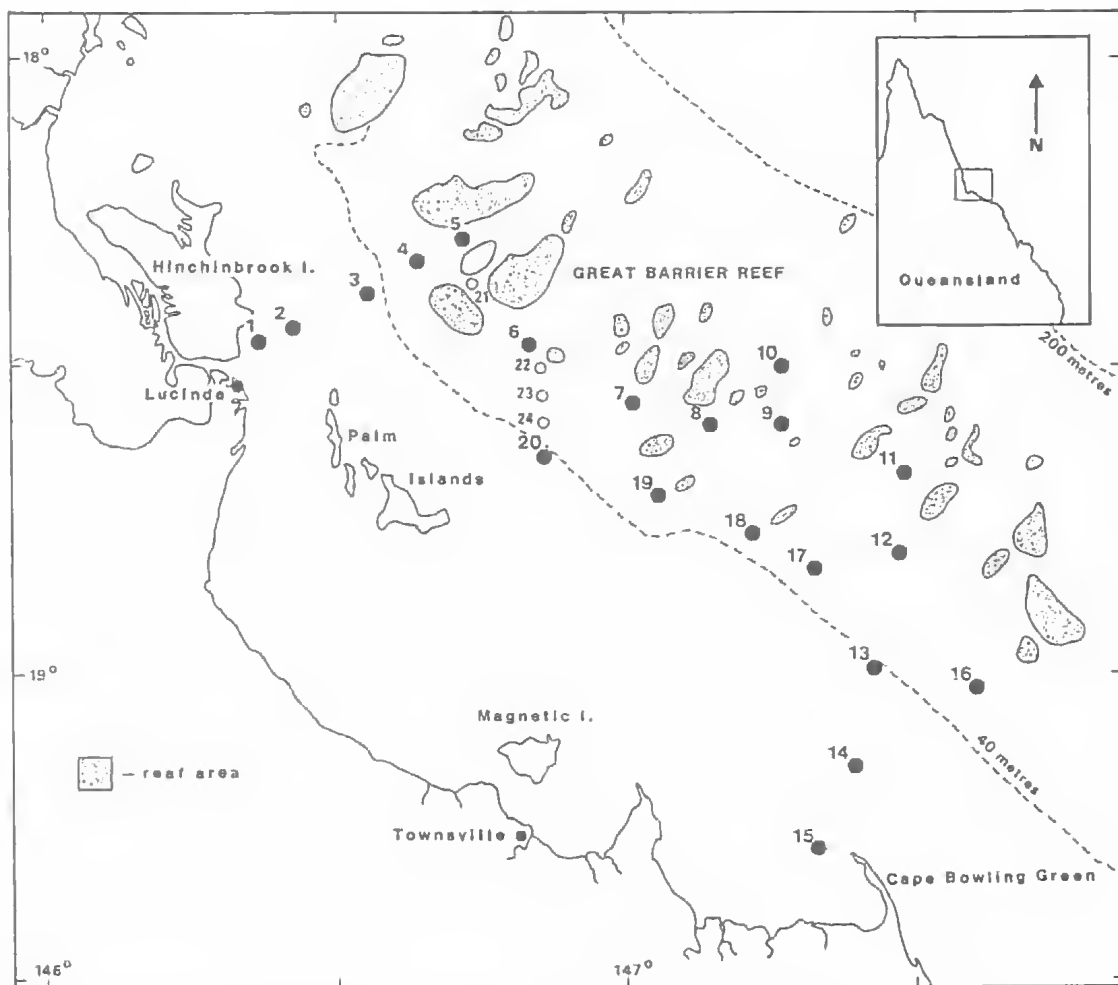

FIG. 1. Sampling stations. Stations 1 to 20 sampled each month from January to December 1985. Stations 1 to 6, 20 and additional stations 21 to 24 were sampled from January to June 1986.

Research officers conducted the sampling from the Fisheries Research Vessel 'Gwendoline May', a 20 m steel trawler, on consecutive nights around the time of new moon. The 'Gwendoline May' was equipped with commercial trawling gear: two 'Florida Flyer' nets, each of 12-metre headline length. The starboard net was made of 50 mm mesh, which is standard for the fishery; the port net was 40 mm mesh, which facilitated the capture of juvenile prawns.

For each sample, the nets were towed at 6 km/hr over the bottom and parallel to the depth contour, for approximately thirty minutes. Upon retrieval, the catch from each net was spilt onto a divided sorting tray. Catch sub-samples were taken from the standard commercial net (starboard), unless gear failure necessitated the

use of the port net's catch. The total catch of the starboard net was weighed after sponges, sea snakes, stingrays, shovel-nose sharks and other large elements had been recorded and removed. Each sub-sample (approx. 10 kg) was thoroughly washed in sea-water, weighed, labelled and frozen in a plastic tray. The remaining catch was sorted and species not previously recorded from the survey were retained for positive identification to augment the species list.

All catch sub-samples were sorted at the Northern Fisheries Research Centre in Cairns. Most fish, crustaceans, echinoderms, and molluscs were identified to species level. Other faunal elements were identified to family level or beyond, in most cases. The numerical abundance (number of individuals) of each

species within the sub-sample was also recorded. Extrapolating from the sub-sample, the number of each species in the total catch was then calculated. Biomass and size data for individual taxa were not collected.

While all fish, crustacean and mollusc species have been confirmed by staff of the Queensland

Museum, the identifications of the other taxa are provisional only. It was not possible within the scope of this study to specifically identify Porifera, Cnidaria, Sipuncula, Annelida and Bryozoa. For the purposes of comparison with the published results of other faunal surveys, 'demersal fauna' refers to the total trawled catch of fish and macro-invertebrates.

TABLE 1. Commercially important species within the central Queensland prawn trawl fishery. Proportions given were based on the 1985/86 catch. Annual production, particularly for scallops can be highly variable. These percentages are not indicative of the relative monetary value of each species.

Species	Common Name	Estimated proportion of annual commercial catch by weight (%)	Comments
<i>Penaeus longistylus</i>	Red-spot king prawn	32.5	target species of 'king prawn' fishery
<i>P. latisulcatus</i>	Blue-leg king prawn	13.5	target species of 'king prawn' fishery
<i>P. esculentus</i>	Brown tiger prawn	9.0	target species of 'tiger prawn' fishery
<i>P. semisulcatus</i>	Grooved tiger prawn	9.0	target species of 'tiger prawn' fishery
<i>P. merguensis</i>	Banana prawn	12.0	incidental species of 'tiger prawn' fishery; target species when abundant
<i>P. monodon</i>	Leader prawn	0.5	incidental species of 'tiger prawn' fishery
<i>Metapenaeus endeavouri</i>	Endeavour prawn	1.0	incidental species of 'tiger prawn' fishery
<i>M. ensis</i>	False endeavour prawn	4.0	incidental species of both fisheries
<i>Thenus sp.1</i>	Bay lobster ('sand bug')	10.0	incidental species of 'king prawn' fishery
<i>T. orientalis</i>	Bay lobster ('mud bug')	4.0	incidental species of 'tiger prawn' fishery
<i>Amusium balloti</i>	Saucer scallop	1.5	incidental and target species of the 'king prawn' fishery
<i>Metapenaeopsis mogiensis</i> , <i>M. palmensis</i> , <i>M. rosea</i> , <i>Trachypenaeus anchoralis</i> , <i>T. curvirostris</i> , <i>T. granulosus</i> , <i>T. fulvus</i>	Coral prawns	3.0	incidental species of the 'king prawn' fishery Species not separated

RESULTS

A total of 477 taxa were identified from the survey, of which 18 (3.8%) were commercially important (Table 1). Fish and crustaceans were the most abundant components of the catch and accounted for 38% and 42% respectively of the total number of individuals caught (Table 2).

The relative abundance of each species over the entire survey was ranked according to the criteria: rare — less than 100 individuals captured; common — between 100 and 1000 individuals captured; abundant — more than 1000 individuals captured. A systematic list of all taxa is provided in the Appendix. The species ranked abundance and a list of stations at which it was caught is given for each taxa.

The majority of fish gathered were small benthic species of between 10 and 20 cm total length. Flatfish (particularly Bothidae and Paralichthyidae), goatfish (Mullidae), leatherjackets (Monacanthidae), grinders (Synodontidae) and threadfin bream (Nemipteridae) were the most numerous groups (Table 3). Fish species constituted around 75% of the biomass of the catch (Table 2).

Commercially important fish species (particularly Lutjanidae, Lethrinidae and Serranidae) were represented by small juvenile individuals only and they occurred infrequently.

Few of the species collected were considered to be typical coral reef associated fishes (see Russell, 1983). A comparison of the relative number of species in the 10 most speciose reef fish families (Table 4) indicated that the trawled fish fauna was dissimilar to that of the reef.

Crustacean catch was numerically dominated by portunid crabs (30%), small penaeid prawns (61%) (collectively referred to as coral prawns, see Table 1) and the targeted commercial prawns (8%). Despite their numerical abundance and commercial importance, crustaceans represented only 20% of the total biomass of the catch.

Maretia planulata, a small urchin, was the most numerous echinoderm and occasionally dominated a trawl catch. All other echinoderm species and species groups were uncommon. Their number in any one catch rarely exceeded 20 individuals and their contribution to the total catch weight was negligible.

DISCUSSION

The demersal fauna associated with the central Queensland king prawn fishery was characterised by high species diversity and low numerical abundance within individual taxa.

TABLE 2. Abundance and biomass of major taxonomic groups

Group	Abundance of Taxa		Abundance of Individuals %	Biomass %*
	Number	%		
Pisces	272	57	38.3	75

REMAINING TAXA	237	31.4
TOTAL	272	100.0

* Only includes common species (present in 5% or more of samples).

TABLE 4. Comparison of the proportion (%) of species in ten fish families, representing coral reefs of the Great Barrier Reef and from the trawled fauna adjacent to coral reefs. Fish families selected were the ten most speciose families listed by Russell (1983).

Family	GBR	Trawled fauna
Gobiidae	12.1	0.7
Labridae	8.0	1.9
Pomacentridae	8.0	0.4
Blennidae	4.7	0.7
Apogonidae	3.8	6.3
Serranidae	3.7	3.0
Chaetodontidae	3.7	0.7
Acanthuridae	2.9	0.0
Muraenidae	2.7	0.7
Scaridae	2.6	0.0

Spatial variability in catch composition was pronounced (Watson and Goeden, M.S.). Dominance by an individual species or species group in a catch sample was rare although aggregations of the urchin *M. planulata* were evident from some samples. It is unlikely that their occurrence represented a static '*M. planulata* Community'.

Compared with the demersal trawl fisheries throughout the south-east Asian region (Pauly, 1979), Australia's tropical trawl fisheries are particularly selective in their target species. In Australia, these fisheries are based on large penaeid prawns, and there is only a secondary interest in a few incidental catch components such as bay lobsters (*Thenus* spp.) and squid (Lolliginidae). Despite the economic forces which have led to these differences, the species diversity of the trawled fauna reported from this survey is very similar to that documented for demersal faunas of north-eastern Australia and the south-east Asian region.

Examination of the species composition of the demersal faunas for the Gulf of Carpentaria (see Rainer, 1984, and references therein), the Gulf of Papua (see Watson, 1984, and references therein) and the coastal region of South-east Asia (see Shindo, 1973; Pauly, 1979, and references therein) indicates that the demersal trawl fauna of the central Queensland coast is tropical west Pacific in affinity. Although the ranked dominance order of taxa (at family level) differed between localities, all of the families listed in Table 3 are similarly dominant throughout the tropical west Pacific region. Over 70% of genera and 50% of species are also shared. The demersal trawl fauna represented only a small

proportion of species endemic to the Great Barrier Reef region.

Although the central Queensland trawl fishery differs from others of the tropical west Pacific in its proximity to coral reefs, true reef associated species (Russell, 1983) were poorly represented in the fauna described. This indicates that coral reef faunas are largely discrete from those of the adjacent benthic environment which are subjected to commercial trawling.

ACKNOWLEDGEMENTS

Assistance provided by the staff of the Northern Fisheries Research Centre in the completion of this research is gratefully acknowledged. We acknowledge the Queensland Museum staff who assisted in the identification of sampled specimens. We thank Drs R. Watson and G. Goeden, and Mr R. Garrett and Mr M. Dredge for their appraisal of the manuscript. This research was supported by a grant from the Great Barrier Reef Marine Park Authority.

APPENDIX

Systematic list of taxa recorded from the central Queensland prawn fishery. Each taxon was classified according to its relative abundance as; rare (R), less than 100 individuals sampled; common (C), between 100 and 1000 individuals sampled; abundant (A), more than 1000 individuals sampled. Stations listed are those at which each taxon was present. Adjacent parentheses indicate species not distinguished during sampling.
